

Worked Examples Effects

Theory

The worked examples effect was first introduced in 1985¹⁾ suggesting positive effects of providing a learner with an example of the problem solution before requiring him to solve one on his own.

This suggestion is contrary to many [constructivist discovery learning](#) methods which suggest a learner should try to solve the problem by himself. [Cognitive load theory](#) on the other hand suggests that searching for the problem solution places unnecessary load on the learner's mind preventing him from learning. A worked example will remove the load of searching for a solution and enable easier acquisition of basic steps leading to the solution.

Practice

$$\begin{aligned}
 & 2x^2 - 6x + 4 = 0 \\
 & \frac{2x^2 - 6x + 4}{2} = \frac{0}{2} \\
 & x^2 - 3x + 2 = 0 \\
 & x^2 - 3x + 2 = (x - 1)(x - 2) = 0 \\
 & x - 1 = 0 \quad \text{or} \quad x - 2 = 0 \\
 & x = 1 \quad \text{or} \quad x = 2
 \end{aligned}$$

Learners should be presented with a worked example of the procedure they're expected to learn prior to trying to solving a problem which requires that procedure. For example, when teaching learners the formula for calculating roots of a quadratic formula, learners should first be provided with a worked example of using the formula, and then try to solve a problem on their own.
